

Comprehensive Trading System Audit

1. High-Level Architecture

The system follows a correct conceptual structure but lacks production-grade separation and robustness.

2. Critical Issues

- Virtual environment (.venv) committed → bloated repo and security risk
- No backend service layer → tightly coupled architecture
- No persistent state → trade inconsistencies
- No broker reconciliation → incorrect PnL and positions
- Hardcoded parameters → no adaptability
- No latency optimization → inefficient execution
- Frontend mostly boilerplate → not integrated with trading system

3. Strategy Audit

ANN Bot: Too small, lacks feature engineering and proper training pipeline.

Saviour Combo: Risky grid-like strategy with potential for large drawdowns.

4. Execution Engine Issues

Missing order lifecycle tracking, retry logic, and slippage control.

5. Dashboard Issues

No real-time updates, WebSocket integration, or proper trading metrics.

6. Risk Management Gaps

Missing kill switch, capital allocation logic, and volatility-based risk control.

7. System Design Problems

Monolithic structure and lack of service separation.

8. Recommended Architecture

9. Roadmap

Phase 1: Stability → logging, DB, reconciliation

Phase 2: Correctness → order tracking, retries

Phase 3: Performance → cloud deployment, async execution

Phase 4: Alpha → better ML + features

10. Conclusion

This is a strong prototype but not yet production-grade. Key risks include trade miscounts, execution failures, and lack of synchronization with broker.
